Natural Language Processing with Deep Learning

Lecture 2 — Mathematical foundations of deep learning

Prof. Dr. Ivan Habernal

October 20, 2023

Natural Language Processing Group Paderborn University We focus on Trustworthy Human Language Technologies

www.trusthlt.org

Motivation

Motivation

Problem 1: Minimize functions

Problem 2: Minimize multivariate functions

Problem 3: When functions become heavily nested

Efficient computation of gradient

Quick poll

- 1. Who of you knows stochastic gradient descent and backpropagation?
- 2. Who of you ever implemented it from scratch?

How does this lecture relate to the previous one and to entire course?

How deep will we go?

We won't cover

- Set theory: The assembler of mathematics
 - Sets $A = \{a, b, c\}, a \in A$, no ordering
 - Ordered tuples $(a, b) \neq (b, a)$
- Number theory
 - Set of natural numbers $\mathbb{N}_0 = \{0, 1, \ldots\}$
 - Set of real numbers \mathbb{R} , infinity
- Sequences and limits

 $\mathbb{R}^2 = \mathbb{R} \times \mathbb{R}$ — tuples of reals, e.g., (1.3, -44.67), also a two-dimensional vector

Problem 1: Minimize functions

Motivation

Problem 1: Minimize functions

Problem 2: Minimize multivariate functions

Problem 3: When functions become heavily nested

Efficient computation of gradient

Why is it important?

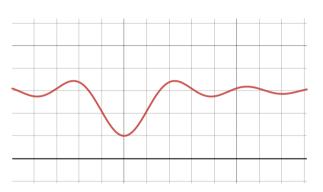

In supervised machine learning ...

- We have some training data (e.g., for classification)
- We have a learning algorithm
- We want to minimize some kind of error (e.g., misclassification) of the learning algorithm on training data

Problem: Find minimum of any function

- For "easy" functions, closed-form solution (high school math)
- For complicated functions not trivial and cumbersome

Function of single variable

We typically use Euler's notation with arbitrary but somehow standard naming conventions (x, y, f)

$$y = f(x)$$
 $f: \mathbb{R} \to \mathbb{R}$

 $f: A \to B$ where A is domain, B is co-domain

Function composition

$$f: \mathbb{R} \to \mathbb{R}$$
 $g: \mathbb{R} \to \mathbb{R}$

$$h = g \circ f$$

$$h(x) = g(f(x)) \text{ or } (g \circ f)(x) = g(f(x))$$

Lines in two dimensions

Lines in a Cartesian plane are characterized by linear equations.

Every line L (including vertical lines) is the set of all points whose coordinates (x,y) satisfy a linear equation:

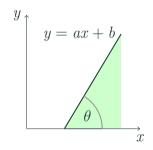

$$L = \{(x, y) \mid w_1 x + w_2 y = w_3\}$$

where w_1 , w_2 and w_3 are fixed real numbers (called coefficients) such that w_1 and w_2 are not both zero.

Linear function in two dimensions

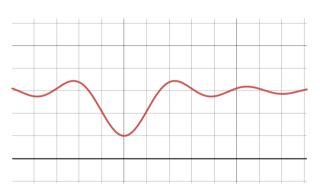

Usually we use **slope-intercept** form y = ax + b

$$\theta = \arctan(a)$$
 $a = \tan(\theta)$

Approximate function by a line at point

"Steepness" at c?

$$f'(c) = \lim_{x \to c} \frac{f(x) - f(c)}{x - c}$$

The derivative of f at c

Derivative-computing function

We want a function D which, when given a differentiable function $f: \mathbb{R} \to \mathbb{R}$ as input, produces another function $q:\mathbb{R}\to\mathbb{R}$ output, such that q(c)=f'(c) for every c.

This derivative-computing function D is often written as

$$\frac{d}{dx}$$

but this causes inconsistent notation like

$$\frac{d}{dx}(f), \qquad \frac{df}{dx}, \qquad \frac{dy}{dx}$$

and forces one to choose a variable name x or y

Derivative of nested functions: The chain rule hammer

Variant 1 (Lagrange's notation)

Let $f, g : \mathbb{R} \to \mathbb{R}$ be two functions which have derivatives. Then the derivative of q(f(x)) is $q'(f(x)) \cdot f'(x)$

Variant 2 (Function composition operator ○)

Let $f, g : \mathbb{R} \to \mathbb{R}$ be two functions which have derivatives. Let $h = g \circ f$. The derivative of h is $h' = (g \circ f)' = (g' \circ f) \cdot f'$

Variant 3 (Leibnitz's notation)

Call h(x) = g(f(x)). Then using $\frac{dh}{dx}$ for the derivative of h, the chain rule for this would be $\frac{dh}{dx} = \frac{dh}{dt} \frac{df}{dx}$

Chain rule example

Consider $y = e^{\sin(x^2)}$. Composite of three functions:

$$y = f(u) = e^{u}$$

$$u = g(v) = \sin v = \sin(x^{2})$$

$$v = h(x) = x^{2}$$

Their derivatives are

$$\frac{dy}{du} = f'(u) = e^u = e^{\sin(x^2)}$$
$$\frac{du}{dv} = g'(v) = \cos v = \cos(x^2)$$
$$\frac{dv}{dx} = h'(x) = 2x$$

Chain rule example (cont.)

Consider $y = e^{\sin(x^2)}$. Composite of three functions:

$$y = f(u) = e^u$$
, $u = g(v) = \sin v = \sin(x^2)$, $v = h(x) = x^2$

Their derivatives are

$$\frac{dy}{du} = e^{\sin(x^2)}, \frac{du}{dv} = \cos(x^2), \frac{dv}{dx} = 2x$$

Derivative of their composite at the point x = a is (in Leibniz notation)

$$\frac{dy}{dx} = \frac{dy}{du}\Big|_{u=g(h(a))} \cdot \frac{du}{dv}\Big|_{v=h(a)} \cdot \frac{dv}{dx}\Big|_{x=a}$$

We want $\hat{x} = \operatorname{argmin}_x f(x)$

Pre-requisites:

- We can evaluate y = f(x) for any x
- We can evaluate its derivative f'(c) (or $\frac{dy}{dx}(c)$) for any c

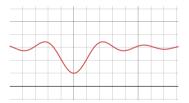

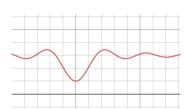

Figure 1: $3 - \frac{\sin(2x)}{x}$

Gradient-based optimization: Find minimum of a function

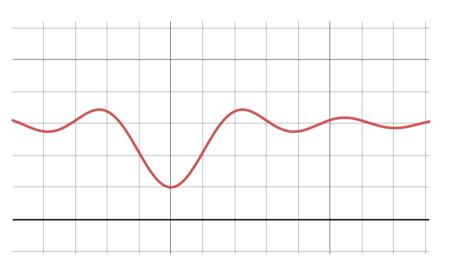

- 1. Start with initial random value x_i
- 2. $u = f'(x_i)$ direction and strength of change at x_i
- 3. Next value $x_{i+1} \leftarrow x_i \eta \cdot u$
- 4. With small enough η (eta), $f(x_{i+1}) < f(x_i)$

Repeating 2 + 3 (with properly decreasing values of η) will find minimum point x_i

Gradient-based optimization: Workout example

Problem 2: Minimize multivariate functions

Motivation

Problem 1: Minimize functions

Problem 2: Minimize multivariate functions

Problem 3: When functions become heavily nested

Efficient computation of gradient

Multivariate functions

 $f: \mathbb{R}^n \to \mathbb{R}$

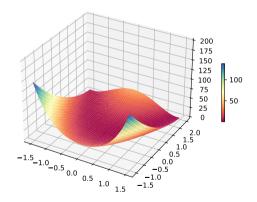

Figure 2: $f(x, y) = (a - x)^2 + b(y - x^2)^2$, a = 1, b = 100

Partial derivatives

Partial derivative: the directional derivative wrt. a single variable

 $\frac{\partial f}{\partial x_0}$ — "the partial derivative of f with respect to x_2 "

Example:
$$f(x_1, x_2, x_3) = (x_1)^2 x_2 + \cos(x_3)$$

$$\frac{\partial f}{\partial x_1} = 2x_2 x_1 \qquad \frac{\partial f}{\partial x_2} = (x_1)^2 \qquad \frac{\partial f}{\partial x_3} = -\sin(x_3)$$

Gradient

Example:
$$f(x_1, x_2, x_3) = (x_1)^2 x_2 + \cos(x_3)$$

$$\frac{\partial f}{\partial x_1} = 2x_2 x_1 \qquad \frac{\partial f}{\partial x_2} = (x_1)^2 \qquad \frac{\partial f}{\partial x_3} = -\sin(x_3)$$

The resulting total derivative matrix Df is called the **gradient** of f, denoted ∇f

Example:
$$f(x_1, x_2, x_3) = (x_1)^2 x_2 + \cos(x_3)$$

$$\nabla f = \begin{pmatrix} \frac{\partial f}{\partial x_1} & \frac{\partial f}{\partial x_2} & \frac{\partial f}{\partial x_3} \end{pmatrix} = \begin{pmatrix} 2x_2x_1 & (x_1)^2 & -\sin(x_3) \end{pmatrix}$$

Gradient properties

Example:
$$f(x_1, x_2, x_3) = (x_1)^2 x_2 + \cos(x_3)$$

$$\nabla f = \begin{pmatrix} \frac{\partial f}{\partial x_1} & \frac{\partial f}{\partial x_2} & \frac{\partial f}{\partial x_3} \end{pmatrix} = \begin{pmatrix} 2x_2x_1 & (x_1)^2 & -\sin(x_3) \end{pmatrix}$$

For every differentiable function $f: \mathbb{R}^n \to \mathbb{R}$ and every point $\boldsymbol{x} \in \mathbb{R}^n$, the gradient $\nabla f(\boldsymbol{x})$ points in the direction of steepest ascent of f at x.

Warning!

Sometimes we call gradient the function for computing concrete values for a given input (as above), sometimes the vector of concrete numbers computed for the given input

Gradient descent for minimizing multivariate functions Upapersory

Given $f: \mathbb{R}^n \to \mathbb{R}$ we want to find

$$\hat{\boldsymbol{x}} = \operatorname*{argmin}_{\boldsymbol{x}} f(\boldsymbol{x})$$

- 1. Start at some random position with a random value vector $\boldsymbol{x}_i = (x_1, \dots, x_n)$
- 2. Compute the gradient and update the position

$$\boldsymbol{x}_{i+1} \leftarrow \boldsymbol{x}_i - \eta \cdot \nabla f(\boldsymbol{x}_i)$$

3. After enough iterations or some stopping criterion we have \hat{x}

Gradient descent for minimizing multivariate functions A PADERBORN

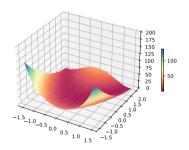

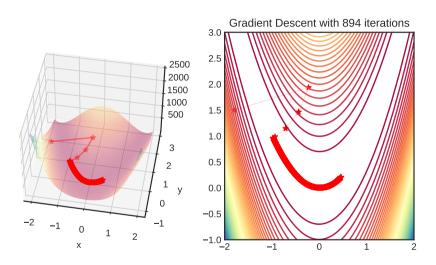

Figure 3: $f(x, y) = (a - x)^2 + b(y - x^2)^2$, a = 1, b = 100

$$\nabla f = (-400xy + 400x^3 + 2x - 2; \quad 200y - 200x^2)$$

Gradient for minimizing multivariate functions

Random starting point (-1.8; 1.5), minimum at (1; 1)

Problem 3: When functions become heavily nested

Motivation

Problem 1: Minimize functions

Problem 2: Minimize multivariate functions

Problem 3: When functions become heavily nested Efficient computation of gradient

In reality we work with deeply composed functions

Example

Minimize function e wrt. w_0, w_1, \ldots, w_K

$$e = -\frac{1}{N} \sum_{i=1}^{N} y_{[i]} \log \left(\frac{1}{1 + \exp\left(w_0 + \sum_{j=1}^{K} w_k \cdot \boldsymbol{x}_{[i][k]}\right)} \right)$$

Where $x_{[1]}, \ldots, x_{[N]}$, and $y_{[1]}, \ldots, y_{[N]}$ are constants

$$\nabla f = \left(\frac{\partial e}{\partial w_0}; \frac{\partial e}{\partial w_1}; \dots; \frac{\partial e}{\partial w_K}\right)$$

Chain Rule for Multivariable Functions

Suppose that x = q(t) and y = h(t) are differentiable functions of t and z = f(x, y) is a differentiable function of x and y. Then z = f(x(t), y(t)) is a differentiable function of t and

$$\frac{\partial z}{\partial t} = \frac{\partial z}{\partial x} \cdot \frac{dx}{dt} + \frac{\partial z}{\partial y} \cdot \frac{dy}{dt}$$

where the ordinary derivatives are evaluated at t and the partial derivatives are evaluated at (x, y).

Be ready for possible notation madness

$$\frac{\partial f}{\partial t} = \frac{\partial f}{\partial g} \frac{\partial g}{\partial t} + \frac{\partial f}{\partial h} \frac{\partial h}{\partial t}$$

Chain rule for multivariable functions (two independent variables)

Suppose x = g(u, v) and y = h(u, v) are differentiable functions of u and v, and z = f(x, y) is a differentiable function of x and y. Then, z = f(g(u, v), h(u, v)) is a differentiable function of u and v, and

$$\frac{\partial z}{\partial u} = \frac{\partial z}{\partial x} \frac{\partial x}{\partial u} + \frac{\partial z}{\partial y} \frac{\partial y}{\partial u}$$
$$\frac{\partial z}{\partial v} = \frac{\partial z}{\partial x} \frac{\partial x}{\partial v} + \frac{\partial z}{\partial y} \frac{\partial y}{\partial v}$$

Problem 3: When functions

Efficient computation of gradient

become heavily nested

Working example

$$e = (a+b)(b+1)$$

Compute gradient wrt. a and b

This one is easy by hand, but that's not the point

$$e = (a+b)(b+1) = ab + a + b^{2} + b$$
$$\frac{\partial e}{\partial a} = b+1 \qquad \frac{\partial e}{\partial b} = a+2b+1$$

Add some intermediate variables and function names

$$e = (a+b)(b+1)$$

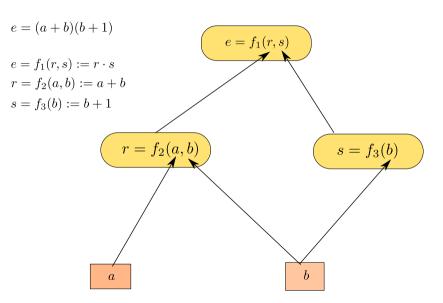

$$e = f_1(r,s) := r \cdot s$$

$$r = f_2(a, b) := a + b$$

$$s = f_3(b) := b + 1$$

Build computational graph and evaluate (forward step) A PADERBORN

Important: a, b will be some concrete real numbers, therefore r, s, e will be concrete real numbers too!

Computational graph

- DAG direct acyclic graph (not necessarily a tree!)
- Each node a differentiable function with arguments
- Leaves variables (e.g., a, b) or constants
- Arrows Function composition

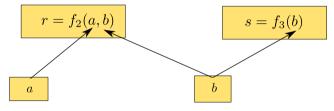

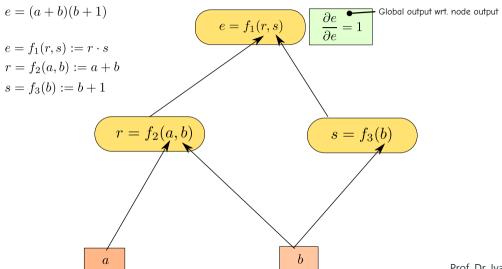

Figure 4: r, s are parents of b; a, b are children (arguments) of r

Goal: $\frac{\partial e}{\partial a}$ and $\frac{\partial e}{\partial b}$ (gradient), but let's do $\frac{\partial e}{\partial \star}$ for every node $\c Q$

Since $e=r\cdot s$, par. derivatives are easy: $\frac{\partial e}{\partial r}=s$ and $\frac{\partial e}{\partial s}=r$

$$e=(a+b)(b+1)$$

$$e=f_1(r,s):=r\cdot s$$

$$r=f_2(a,b):=a+b$$

$$s=f_3(b):=b+1$$

$$r=f_2(a,b)$$

$$r=f_2(a,b)$$

$$s=f_3(b)$$

$$r=f_2(a,b)$$

$$r=f_2(a,b)$$

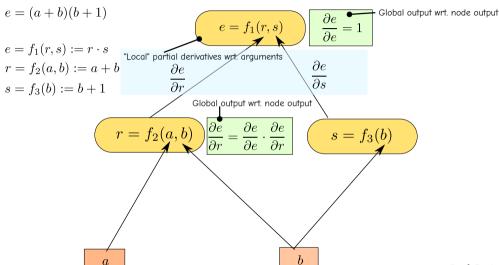

$$r=f_3(b)$$

$$r=f_3(b)$$

$$r=f_3(b)$$

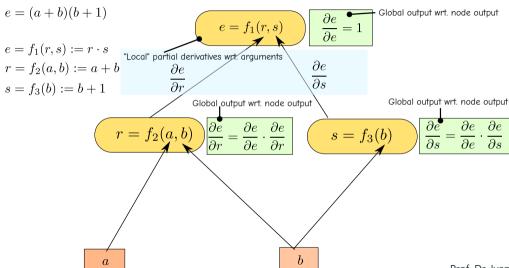

Sanity check: r, s are some concrete real numbers, therefore $\frac{\partial e}{\partial x}$ and $\frac{\partial e}{\partial x}$ will be concrete real numbers too!

Proceed to next child r and compute $\frac{\partial e}{\partial r}$ – use chain rule!

Proceed to next child s and compute $\frac{\partial e}{\partial s}$ – use chain rule! ψ PADERBORN

Since r=a+b, par. derivatives are easy: $\frac{\partial r}{\partial a}=1$ and $\frac{\partial r}{\partial b}=1$

$$e = (a+b)(b+1)$$

$$e = f_1(r,s) := r \cdot s$$

$$r = f_2(a,b) := a+b$$

$$s = f_3(b) := b+1$$
Global output wrt. node output
$$r = f_2(a,b) \xrightarrow{\partial e} \frac{\partial e}{\partial s}$$
Global output wrt. node output
$$r = f_2(a,b) \xrightarrow{\partial e} \frac{\partial e}{\partial r} \xrightarrow{\partial e} \frac{\partial e}{\partial r}$$

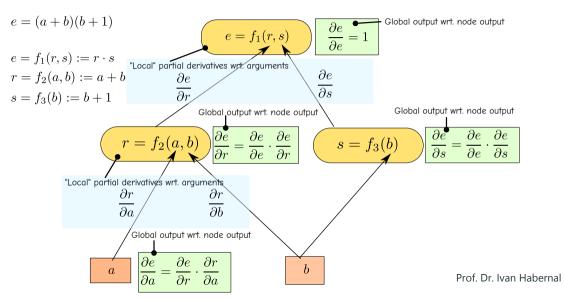

$$s = f_3(b) \xrightarrow{\partial e} \frac{\partial e}{\partial s} = \frac{\partial e}{\partial e} \cdot \frac{\partial e}{\partial s}$$

$$s = f_3(b)$$

$$s = f_3(b)$$

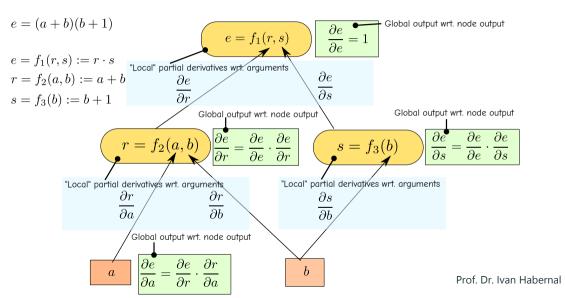

$$s = f_3(b)$$
Frof. Dr. Ivan Habernal

Proceed to next child a and compute $\frac{\partial e}{\partial a}$ – use chain rule!

Since s=b+1, par. derivatives are easy: $\frac{\partial s}{\partial b}=1$

Proceed to b and compute $\frac{\partial e}{\partial b}$ – use multivariate chain rule paperborn

$$e = (a+b)(b+1)$$

$$e = f_1(r,s) := r \cdot s$$

$$r = f_2(a,b) := a+b$$

$$s = f_3(b) := b+1$$
Global output wrt. node output
$$r = f_2(a,b) \qquad \frac{\partial e}{\partial r} = \frac{\partial e}{\partial r} \cdot \frac{\partial e}{\partial r}$$
Global output wrt. node output
$$r = f_2(a,b) \qquad \frac{\partial e}{\partial r} = \frac{\partial e}{\partial r} \cdot \frac{\partial e}{\partial r}$$

$$\frac{\partial e}{\partial s} = \frac{\partial e}{\partial s} \cdot \frac{\partial e}{\partial s}$$

$$\frac{\partial e}{\partial s} = \frac{\partial e}{\partial s} \cdot \frac{\partial e}{\partial s}$$
"Local" partial derivatives wrt. arguments
$$\frac{\partial r}{\partial a} \qquad \frac{\partial r}{\partial b}$$
Global output wrt. node output
$$\frac{\partial s}{\partial b} \qquad \frac{\partial s}{\partial b}$$
Global output wrt. node output
One out

Goal: $\nabla e = \left(\frac{\partial e}{\partial a}; \frac{\partial e}{\partial b}\right)$ — we computed it for concrete a and \mathbf{d} PADERBORN

$$e = (a + b)(b + 1)$$

Generic node in a computational graph

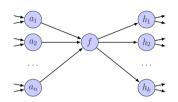

Adapted from J. Kun (2020). *A Programmer's Introduction to Mathematics*. 2nd ed., p. 265

Figure 5: A generic node of a computation graph. Node f has many inputs, its output feeds into many nodes, and each of its inputs and outputs may also have many inputs and outputs.

Generic node in a computational graph $f(a_1, \ldots, a_n)$

Assuming the graph is a function e = g(...), we compute

$$\frac{\partial e}{\partial f} = \sum_{i=1}^{k} \frac{\partial e}{\partial h_i} \cdot \frac{\partial h_i}{\partial f}$$

and

$$\frac{\partial f}{\partial a_i}$$
 for a_i, \dots, a_n

What each node must implement?

For example a function s = f(a, b, c, d)

- How to compute the output value s (given the parameters a, b, c, d)
- How to compute partial derivatives wrt. the parameters, i.e. $\frac{\partial s}{\partial a}$, $\frac{\partial s}{\partial b}$, $\frac{\partial s}{\partial a}$, $\frac{\partial s}{\partial d}$

Backpropagation

- Forward computation: Compute all nodes' output (and cache it)
- Backward computation (Backprop): Compute the overall function's partial derivative with respect to each node

Ordering of the computations? Recursively or build a graph's topology upfront and iterate

Backpropagation: Recap

- We can express any arbitrarily complicated function $f: \mathbb{R}^n \to \mathbb{R}$ as a computational graph
- For computing the gradient ∇f at a concrete point (x_1, x_2, \dots, x_n) we run the forward pass and backprop
- When caching each node's intermediate output and partial derivatives, we avoid repeating computations \rightarrow efficient algorithm

Recap

Motivation

Problem 1: Minimize functions

Problem 2: Minimize multivariate functions

Problem 3: When functions become heavily nested

Efficient computation of gradient

Take aways

- We can quite efficiently find a minimum of any differentiable nested multivariate function
 - Iterative gradient descent takes the most promising direction
 - Backpropagation utilizes computational graphs and caching \rightarrow computes gradients efficiently
- We have not touched neural networks yet at all!
